

# $D \rightarrow K^+ K^- \pi^+ \pi^-$ strong phase analysis and $\gamma$ measurement at LHCb and BESIII

Martin Tat

Oxford LHCb

4th December 2023

## What's happened since my last update in June?

- Very busy summer! Many presentations, holiday, some analysis...
- Analysis: First strong-phase measurement of  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  in phase-space bins complete!
- Today: The combination of LHCb and BESIII, resulting in the first model-independent measurement of  $\gamma$  in this channel

# Brief introduction to my PhD analysis

## Status after 3 years:

- 1 Final piece of my PhD analysis is coming together
- 2 Just started on analysis of November 2022 TORCH testbeam data
- 3 Will probably start writing PhD thesis next term

WWW.PHDCOMICS.COM

# Recap of LHCb analysis of $B^\pm \rightarrow [K^+K^-\pi^+\pi^-]_D h^\pm$

LHCb paper: A study of CP violation in the decays

$$B^\pm \rightarrow [K^+K^-\pi^+\pi^-]_D h^\pm \quad (h = K, \pi) \text{ and } B^\pm \rightarrow [\pi^+\pi^-\pi^+\pi^-]_D h^\pm$$

- Binned model-dependent GGSZ analysis of  $B^\pm \rightarrow [K^+K^-\pi^+\pi^-]_D h^\pm$
- A  $3\sigma$  tension:  $\gamma = (116^{+12}_{-14})^\circ$

**Figure 1:** Left:  $B^\pm \rightarrow DK^\pm$  bin asymmetries. Right: Interpretation of  $\gamma$

## Why is there a $3\sigma$ tension?

- $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  strong phases are from a model
- Model-independent inputs from BESIII are necessary
- It's been challenge to convince reviewers that  $\gamma$  is model dependent:

## Why is there a $3\sigma$ tension?

- $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  strong phases are from a model
- Model-independent inputs from BESIII are necessary
- It's been challenge to convince reviewers that  $\gamma$  is model dependent:

*“ If you plan to keep the model-dependent value of gamma in the paper, the interpretation part should contain more discussion on the model dependence.” - EPJC referee 1*

## Why is there a $3\sigma$ tension?

- $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  strong phases are from a model
- Model-independent inputs from BESIII are necessary
- It's been challenge to convince reviewers that  $\gamma$  is model dependent:

*“If you plan to keep the model-dependent value of gamma in the paper, the interpretation part should contain more discussion on the model dependence.”* - EPJC referee 1

*“A general comment is that in (7 !!) different places [Abstract, Introduction (page 1)...] it is mentioned the same message: that the analysis is model-dependent...”* - EPJC referee 2

# Brief summary of formalism

- Identical formalism to BPGGSZ analyses with  $D^0 \rightarrow K_S^0 h^+ h^-$
- LHCb: Measure CP asymmetries in each bin
- BESIII: Measure the cosine (sine) of the strong-phase difference  $c_i$  ( $s_i$ )

**Figure 2:** Left: Binning scheme of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ , visualised on a Dalitz plot. Right: Analogous binning scheme for  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$ , where the 5D phase space is projected onto the model-predicted  $\delta_D$  and  $r_D$ .

How to measure  $c_i$  and  $s_i$ ? Sneha already introduced BESIII in last week's seminar!

- 1 Measure the double-tag yields
- 2 Tags with different CP content can enhance/suppress yields
- 3 Infer  $c_i$  and  $s_i$  in a large simultaneous fit of all 19 tag modes

# Double tag fit of $KK\pi\pi$ vs $K\pi$

(a) Bin 1 yield:  $84.5^{+9.8}_{-9.1}$

(b) Bin 2 yield:  $211.2^{+15.4}_{-14.8}$

(c) Bin 3 yield:  $181.0^{+14.0}_{-13.3}$

(d) Bin 4 yield:  $88.6^{+9.7}_{-9.0}$

# Double tag fit of $KK\pi\pi$ vs $KK$

(a) Bin 1 yield:  $25.3^{+6.2}_{-5.5}$

(b) Bin 2 yield:  $8.8^{+4.0}_{-3.3}$

(c) Bin 3 yield:  $4.5^{+3.3}_{-2.6}$

(d) Bin 4 yield:  $21.1^{+5.5}_{-4.8}$

# Double tag fit of $KK\pi\pi$ vs $K_S\pi^0$

(a) Bin 1 yield:  $7.9^{+3.1}_{-2.5}$

(b) Bin 2 yield:  $40.4^{+6.8}_{-6.3}$

(c) Bin 3 yield:  $61.1^{+8.3}_{-7.8}$

(d) Bin 4 yield:  $18.3^{+4.5}_{-3.9}$

Can we trust the results? Let's do some toys!

- ① Using model predictions of  $c_i$  and  $s_i$ , predict all DT yields
- ② For each tag mode, generate 1000 toy datasets and fit DT yield
- ③ Run 1000 fits of  $c_i$  and  $s_i$  using fit results from toys
- ④ Plots pulls

# Toy studies

(a)  $c_1$  pulls

(b)  $c_2$  pulls

(c)  $c_3$  pulls

(d)  $c_4$  pulls

# Toy studies

(a)  $s_1$  pulls

(b)  $s_2$  pulls

(c)  $s_3$  pulls

(d)  $s_4$  pulls

## What do the toy fits tell us?

- 1 Small bias in  $c_i$  which can be corrected
- 2  $s_i$  pulls are very asymmetric, and uncertainties are not very reliable

## What do the toy fits tell us?

- ① Small bias in  $c_i$  which can be corrected
- ②  $s_i$  pulls are very asymmetric, and uncertainties are not very reliable

How do we determine reliable uncertainties for  $s_i$ ?

## What do we need?

- Assign correct uncertainties to non-Gaussian parameters
- Obtain a confidence interval with correct 68% coverage

## What do we need?

- Assign correct uncertainties to non-Gaussian parameters
- Obtain a confidence interval with correct 68% coverage

## How do we achieve this?

- Feldman-Cousins method
- Also known as “Plugin” method in GammaCombo
- It’s a “brute-force” approach to constructing a confidence interval

## How to implement Feldman-Cousins method?

At each scan point of  $s_1$ , perform these fits to data:

- 1 Fit with all parameters floating, and save the log-likelihood  $\chi^2$
- 2 Fit with  $s_1$  fixed to scan point, and save  $\chi_{\text{fix}}^2$
- 3 Calculate  $\Delta\chi_{\text{data}}^2 = \chi_{\text{fix}}^2 - \chi^2$

We expect  $\Delta\chi_{\text{data}}^2$  to become large as we move away from best-fit value, but without direct knowledge of underlying PDF, we cannot determine any confidence intervals from this

## How to implement Feldman-Cousins method?

At each scan point of  $s_1$ , perform toy studies:

- 1 Fix  $s_1$  to scan point and generate 1000 toys
- 2 Perform fits to each toy, with  $s_1$  both floating and fixed
- 3 Calculate  $\Delta\chi_{\text{toy}}^2$

At each scan point, the fraction of toys with  $\Delta\chi_{\text{toy}}^2 > \Delta\chi_{\text{data}}^2$  is equal to  $1 - \text{CL}$ , and the exact 68% confidence interval can then be obtained using an interpolation between points

# Toy studies

Feldman Cousins scan of  $s_1$

(a)  $s_1$

Feldman Cousins scan of  $s_2$

(b)  $s_2$

Feldman Cousins scan of  $s_3$

(c)  $s_3$

Feldman Cousins scan of  $s_4$

(d)  $s_4$

# Fit results

$$c_1 = -0.37 \pm 0.13 \pm 0.01, \quad s_1 = -0.19^{+0.21}_{-0.62} \pm 0.04,$$

$$c_2 = 0.82 \pm 0.05 \pm 0.01, \quad s_2 = -0.23^{+0.12}_{-0.23} \pm 0.03,$$

$$c_3 = 0.86 \pm 0.05 \pm 0.01, \quad s_3 = 0.56^{+0.17}_{-0.35} \pm 0.06,$$

$$c_4 = -0.35 \pm 0.13 \pm 0.01, \quad s_4 = -0.59^{+0.47}_{-0.18} \pm 0.05,$$

- ① Paper was ready at the start of MT
- ② Main result:  $c_i$  and  $s_i$
- ③ Additional measurement:  
 $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  branching fraction
- ④ Bonus measurement: Simultaneous determination of  $\delta_D^{K\pi}$

Measurement of the strong-phase difference between  $D^0$  and

$$\bar{D}^0 \rightarrow K^+ K^- \pi^+ \pi^- \text{ in bins of phase space}$$

(Dated: 99th December 2023)

A first determination of the strong-phase difference between  $D^0$  and  $\bar{D}^0 \rightarrow K^+ K^- \pi^+ \pi^-$  in the decay  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  is performed using 7.91 fb<sup>-1</sup> of  $e^+e^- \rightarrow \psi(3770) \rightarrow D\bar{D}$  data collected by the BESIII detector. The measurements are made in four pairs of bins in phase space, which are chosen to provide optimal sensitivity to the angle  $\gamma$  of the Unitarity Triangle in  $B^\pm \rightarrow DK^\pm$  decays. From these measurements, it follows that the  $CP$ -even fraction of the decay is  $F_+ = 0.744 \pm 0.016_{\text{stat.}} \pm 0.008_{\text{sys.}}$ . In addition, the branching fraction of  $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$  decays is measured to be  $(2.76 \pm 0.05_{\text{stat.}} \pm 0.03_{\text{sys.}}) \times 10^{-3}$ , which is significantly more precise than previous results obtained at other experiments.

## I. INTRODUCTION

In the Standard Model (SM), all  $CP$ -violation phenomena in the quark sector can be described by the Cabibbo-Kobayashi-Maskawa (CKM) matrix [1, 2]. The unitarity nature of this matrix leads to a set of relations that may be represented as triangles in the complex plane. One of these representations, the so-called Unitarity Triangle (UT), has particular importance in flavor-physics studies as all its parameters may be conveniently measured in the decays of  $b$  hadrons [3].

In order to test the SM description of  $CP$  violation, it is important to verify that all measurements of the sides and angles of the UT are self consistent. In this task, measurements of the angle  $\gamma$  (sometimes denoted  $\phi_3$ ) =  $\arg(-V_{cb}V_{ub}^*/V_{cs}V_{us}^*)$  are of particular importance, as they involve only tree-level processes, which are assumed to be dominated by SM contributions and have negligible theoretical uncertainties [4]. Hence, these measurements provide an important benchmark of the SM, which may be compared to indirect determinations of  $\gamma$  arising from measurements of other parameters of the UT that are more susceptible to any New Physics effects lying beyond our present knowledge.

The angle  $\gamma$  can be measured using  $B^\pm \rightarrow DK^\pm$  decays, where  $D$  is a superposition

# BESIII analysis review: a brief summary (paraphrased)

Finally, today, at 10:24:

\*\*\* Discussion title: BESIII Members

Dear all,

Because Yue and Yingrui are too busy recently, to avoid long time delay, PCs have to consider how to speed up with review procedure of this analysis. We decide to update the Referee Committee of BAM702 analysis as below.

We are pleased to announce that a new referee committee is formed for the analysis, "BAM-00754: Binned strong phase difference between  $D^0$  and  $D^0\text{-bar}$   $\rightarrow K+K\text{-pi+pi-}$ ", by Martin Tat et al.

Three referees are :

Yu Zhang, [syuzhang@usc.edu.cn](mailto:syuzhang@usc.edu.cn), USC (Chair)

Wenbin Qian, [wenbin.qian@cern.ch](mailto:wenbin.qian@cern.ch), UCAS

Peilian Liu, [liupl@ihep.ac.cn](mailto:liupl@ihep.ac.cn), IHEP

Many thanks for the three referees' kind help.

How to account for non-Gaussian  $s_i$  uncertainties in  $\gamma$  analysis?

- 1 Simultaneous fit of BESIII and LHCb data
- 2 Incorporate  $B^\pm \rightarrow [K^+ K^- \pi^+ \pi^-]_D h^\pm$  bin yields into BESIII fit
- 3 Free parameters:  $\gamma$ ,  $r_B$ ,  $\delta_B$ ,  $F_i$ ,  $c_i$ ,  $s_i$ ,  $K_i$ , etc

Long term plan: Make some likelihood code for  $c_i$  and  $s_i$  available

# Combined BESIII and LHCb fit of $\gamma$

Cross check with model-dependent  $c_i$  and  $s_i$ :

Simultaneous LHCb and BESIII fit

$$\gamma = (112 \pm 13)^\circ \text{ as expected}$$

# Combined BESIII and LHCb fit of $\gamma$

Then fit LHCb bin yields  $c_i$  and  $s_i$  simultaneously:

$\gamma = (127 \pm 15)^\circ$ , what happened here?!

Confirm with Feldman-Cousins method:

- Good news:  $c_i$  and  $s_i$  systematic is smaller than expected!
- Bad news: Tension has now increased to  $4\sigma$ !!!
- I have looked for bugs everywhere, any suggestions are welcome

## In summary:

- 1 BESIII analysis done, held up by deadweight in the review committee
- 2 New review committee was appointed today, review restarted
- 3 Model-independent value of  $\gamma$  has a  $4\sigma$  tension with LHCb combination, and I have no idea where the bug is

## Next steps:

- Assist Warwick+Bristol groups with TORCH testbeam data
- Study PID separation with testbeam data
- Make a thesis writing plan

Thanks for your attention!
